

CDS 101/110: Lecture 2.2 Dynamic Behavior

5 October 2015

Goals:

- Learn about phase portraits to visualize behavior of dynamical systems
- Understand different types of stability for an equilibrium point
- Know the difference between local/global stability and related concepts
- Introduction to Lyapunov functions

Reading:

- Åström and Murray, Feedback Systems 2e, Sections 5.1-5.4
- Optional: Skim FBS-2e Chapter 4

Dynamic Behavior (and Stability)

Phase Portraits (2D systems only)

Phase plane plots show 2D dynamics as vector fields & stream functions • $\dot{x} = f(x, u(x)) = F(x)$

• Plot F(x) as a vector on the plane; stream lines follow the flow of the arrows

Equilibrium Points

Equilibrium points represent stationary conditions for the dynamics

The equilibria of the system $\dot{x} = f(x)$ are the points x_e such that $f(x_e) = 0$.

$$\frac{dx}{dt} = \begin{bmatrix} x_2 \\ \sin x_1 - \gamma x_2 \end{bmatrix} \qquad \Rightarrow \qquad x_e = \begin{bmatrix} \pm n\pi \\ 0 \end{bmatrix}$$

Stability of Equilibrium Points

N

0.5

N

An equilibrium point is:

Stable if initial conditions that start near the equilibrium point, stay near

- Also called "stable in the sense." of Lyapunov
- For all $\varepsilon > 0$, there exists $\delta s. t.$

$$\|x(0) - x_a\| < \delta \implies \|x(t) - x_a\| < \epsilon$$

Asymptotically stable if all nearby initial conditions converge to the equilibrium point

Stable + converging

Unstable if some initial conditions diverge from the equilibrium point

 May still be some initial conditions that converge

6

Example #1: Double Inverted Pendulum

Two series coupled pendula

- •States: pendulum angles (2), velocities (2)
- •Dynamics: F = ma (balance of forces)
- Dynamics are very nonlinear

Stability of equilibria

- Eq #1 is stable
- Eq #3 is unstable
- Eq #2 and #4 are unstable, but with some stable "modes"

Stability of Linear Systems

Linear dynamical system with state $x \in \mathbb{R}^{n}$:

$$\frac{dx}{dt} = Ax \qquad x(0) = x_0,$$

Stability determined by the eigenvalues $\lambda(A) = \{s \in \mathbb{C} : det(sI - A) = 0\}$

Simplest case: diagonal A matrix (all eigenvalues are real)

Block diagonal case (complex eigenvalues)

 $\frac{dx}{dt} = \begin{bmatrix} \sigma_1 & \omega_1 & 0 & 0 \\ -\omega_1 & \sigma_1 & 0 & 0 \\ 0 & 0 & \ddots & \vdots & \vdots \\ 0 & 0 & \sigma_m & \omega_m \\ 0 & 0 & -\omega_1 & \sigma_m \end{bmatrix} x \quad x_{2j-1}(v) = e^{\sigma_j t} (x_i(0) \sin \omega_j t - x_{i+1}(0) \cos \omega_j t)$ $x_{2j}(t) = e^{\sigma_j t} (x_i(0) \sin \omega_j t - x_{i+1}(0) \cos \omega_j t)$ $x \quad System is asy stable if Re \lambda_i = \sigma_i < 0$

$$\begin{aligned} x_{2j-1}(t) &= e^{\sigma_j t} \big(x_i(0) \cos \omega_j t + x_{i+1}(0) \sin \omega_j t \big) \\ x_{2j}(t) &= e^{\sigma_j t} \big(x_i(0) \sin \omega_j t - x_{i+1}(0) \cos \omega_j t \big) \end{aligned}$$

Theorem linear system is asymptotically stable if and only if **Re**, $\lambda_i < 0 \quad \forall \lambda_i \in \lambda(A)$

Local Stability of Nonlinear Systems

Asymptotic stability of the linearization implies *local* asymptotic stability of equilibrium point

• Linearization around equilibrium point captures "tangent" dynamics

$$\dot{x} = F(x_e) + \frac{\partial F}{\partial x}\Big|_{x_e} (x - x_e) + \text{higher order terms} \xrightarrow{approx} \begin{array}{c} z = x - x_e \\ \dot{z} = Az \end{array}$$

- If linearization is *unstable*, can conclude that nonlinear system is *locally unstable*
- If linearization is stable but not asymptotically stable, can't conclude anything about nonlinear system:

$$\dot{x} = \pm x^3 \quad \stackrel{linearize}{\longrightarrow} \quad \dot{x} = 0$$

• linearization is stable (but not asy stable)

• nonlinear system can be asy stable or unstable

 If linearization is asymptotically stable, nonlinear system is locally asymptotically stable

Local approximation particularly appropriate for control systems design

- Control often used to ensure system stays near desired equilibrium point
- If dynamics are well-approximated by linearization near equilibrium point, can use this to design the controller that keeps you there (!)

Example: Stability Analysis of Inverted Pendulum

System dynamics

$$rac{dx}{dt} = egin{bmatrix} x_2 \ \sin x_1 - \gamma x_2 \end{bmatrix}$$
 ,

Upward equilibrium:

 $\theta = x_1 \ll 1 \implies \sin x_1 \approx x_1$

$$rac{dx}{dt} = egin{bmatrix} x_2 \ x_1 - \gamma x_2 \end{bmatrix} = egin{bmatrix} 0 & 1 \ 1 & -\gamma \end{bmatrix} x$$

• Eigenvalues:
$$-\frac{1}{2}\gamma \pm \frac{1}{2}\sqrt{4+\gamma^2}$$

Downward equilibrium:

- Linearize around $x_1 = \pi + z_1$: $\sin(\pi + z_1) = -\sin z_1 \approx -z_1$
- Eigenvalues:

$$\begin{aligned} z_1 &= x_1 - \pi \\ z_2 &= x_2 \end{aligned} \longrightarrow \quad \frac{dz}{dt} = \begin{bmatrix} z_2 \\ -z_1 - \gamma & z_2 \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -1 & -\gamma \end{bmatrix} z \\ & -\frac{1}{2}\gamma \pm \frac{1}{2}\sqrt{-4 + \gamma^2} \end{aligned}$$

Reasoning about Stability using Lyapunov Functions

Basic idea: capture the behavior of a system by tracking "energy" in system

- Find a single function that captures distance of system from equilibrium
- Try to reason about the long term behavior of all solutions

Example: spring mass system

- Can we show that all solutions return to rest w/out explicitly solving ODE?
- Idea: look at how energy evolves in time
 - V(x) > 0 and V(0)=0 in B_r ,
 - $\dot{V} < 0 (\dot{V} \le 0) \text{ in } B_r$
- Start by writing equations in state space form
- Compute energy and its derivative

$$V(x) = \frac{1}{2}kx_1^2 + \frac{1}{2}mx_2^2 \qquad \qquad \frac{dV}{dt} = kx_1\dot{x}_1 + mx_2\dot{x}_2 \\ = kx_1x_2 + mx_2(-\frac{c}{m}x_2 - \frac{k}{m}x_1) = -cx_2^2$$

- Energy is positive $\Rightarrow x_2$ must eventually go to zero
- If x_2 goes to zero, can show that x_1 must also approach zero (Krasovskii-Lasalle)

 $m\ddot{q} + c\dot{q} + kq = 0$

$$\frac{dx}{dt} = \begin{bmatrix} x_2 \\ -\frac{k}{m}x_1 - \frac{c}{m}x_2 \end{bmatrix} \qquad \begin{array}{c} x_1 = q \\ x_2 = \dot{q} \end{array}$$

Local versus Global Behavior

Stability is a *local* concept

- Equilibrium points define the local behavior of the dynamical system
- Single dynamical system can have stable *and* unstable equilibrium points

Region of attraction

• Set of initial conditions that converge to a given equilibrium point

Example #2: Predator Prey (ODE version)

Continuous time (ODE) version of predator prey dynamics:

$$\begin{aligned} \frac{dH}{dt} &= rH\left(1 - \frac{H}{k}\right) - \frac{aHL}{c+H} \quad H \ge 0\\ \frac{dL}{dt} &= b\frac{aHL}{c+H} - dL \qquad L \ge 0. \end{aligned}$$

- Continuous time (ODE) model
- MATLAB: predprey.m (from web page)

Equilibrium points (2)

- ~(20.5, 29.5): unstable
- (0, 0): unstable

Limit cycle

- Population of each species oscillates over time
- Limit cycle is stable (nearby solutions converge to limit cycle)
- This is a *global* feature of the dynamics (not local to an equilibri point)

Simpler Example of a Limit Cycle

Dynamics:

$$rac{dx_1}{dt} = -x_2 - x_1(1 - x_1^2 - x_2^2) \ rac{dx_2}{dt} = x_1 - x_2(1 - x_1^2 - x_2^2).$$

$$\|x\| = 1$$

- Note that limit cycle is an *invariant set*
- From simulation, x(t+T) = x(t) $V(x) = \frac{1}{4}(1 - x_1^2 - x_2^2)^2$

Stability of invariant set

$$egin{aligned} \dot{V}(x) &= (x_1 \dot{x}_1 + x_2 \dot{x}_2)(1 - x_1^2 - x_2^2) \ &= \cdots \ &= -(x_1^2 + x_2^2)ig(1 - x_1^2 - x_2^2ig)^2 \end{aligned}$$

Summary: Stability and Performance

Key topics for this lecture

- Stability of equilibrium points
- Eigenvalues determine stability for linear systems
- Local versus global behavior
